Individual feedback report:

How well do you use your emotions and intuition in decision–making?

Report for: [redacted] (Subject 5)

What this report contains

You completed the Iowa Gambling Task (developed to test the Somatic Marker Hypothesis; see Bechara, Damasio, Damasio, & Anderson, 2013) using PsyToolkit. On each trial you chose one of four options (shown as buttons/circles). You started with a hypothetical $2000 loan and were asked to maximize profit. Options A & B are risky and disadvantageous in the long run (sometimes large wins, but also high fees/penalties); options C & D are safer and advantageous (smaller wins, fewer penalties/fees).

This report gives you personal feedback: Page 2 explains how to read your figures. Page 3 shows what you chose over time (grouped into five blocks of 20 trials), Page 4 shows how quickly you made decisions (reaction time), and Page 5 shows how your money changed. Together these plots help you see whether your choices shifted toward the better options (C & D), whether decisions became faster as you learned, and whether your earnings trended upward.

(pp. 287–295). Routledge.

How to read the figures (and what they suggest)

Use these notes while you look at your plots on the next pages:

- Figure 1 (choices): We group the 100 trials into five 20-trial blocks so patterns are easier to see. Each point shows how many times you picked each option in that block. A & B (red, triangles) are risky in the long run; C & D (green, circles) are safer. Interpreting: a common learning pattern is a shift toward C/D in later blocks—more C/D → fewer penalties → better long-term outcome.

- Figure 2 (reaction time): The dot is your typical (median) time; the vertical bar shows where most of your times fell (middle 50%). Interpreting: as helpful 'somatic markers' develop, some people slow a bit mid-task while a hunch forms, then speed up once the strategy clicks. Persistently low RT with A/B can reflect chasing immediate rewards; persistently high RT without a shift to C/D can reflect uncertainty/over-deliberation.

- Figure 3 (money): This is your cumulative earnings. The dashed red line is $0 (break-even). Because the task starts with a $2000 loan, going above the red line means you've repaid the loan and are now in profit. Interpreting: an upward trend—especially later—usually pairs with more C/D; flat/down lines often reflect frequent penalties (more A/B).

Figure 1 — Your choices across the task (Subject 5)

Trials are grouped into 5 blocks of 20. Each point shows how many times you picked each option in that block. Options A & B (red, triangles) are risky/disadvantageous; C & D (green, circles) are safer/advantageous. Faint dashed grey = class average.

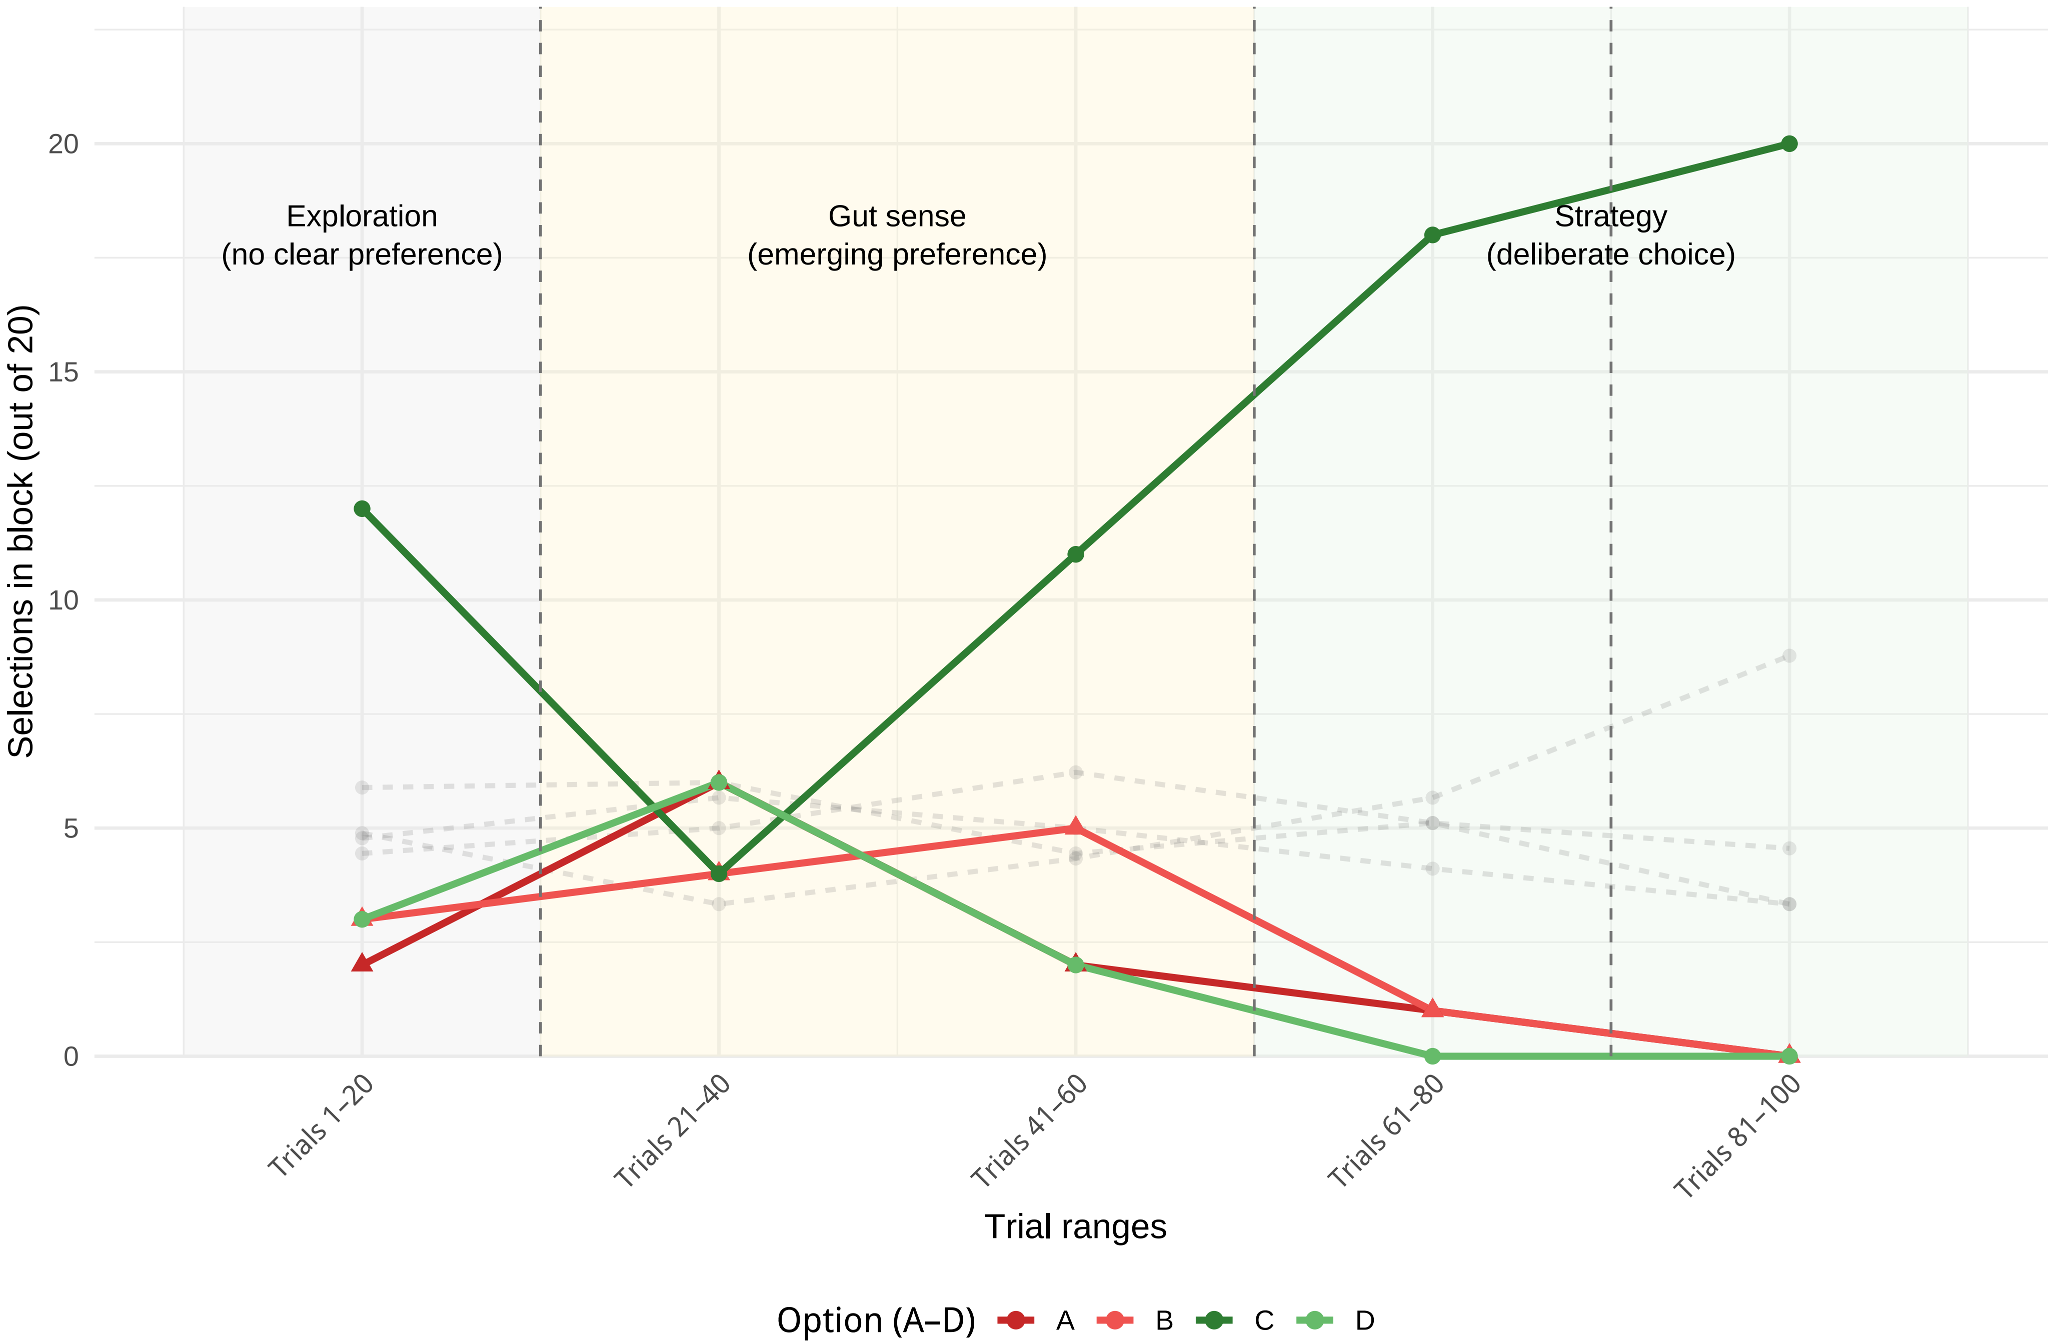

Figure 2 — Reaction time by block (Subject 5)

Dot = your typical (median) reaction time. The vertical bar shows where most of your times fell — the middle 50% (between the 25th and 75th percentiles). Higher RT = more deliberate System 2; lower RT = more intuitive System 1. Faint dashed grey = class average.

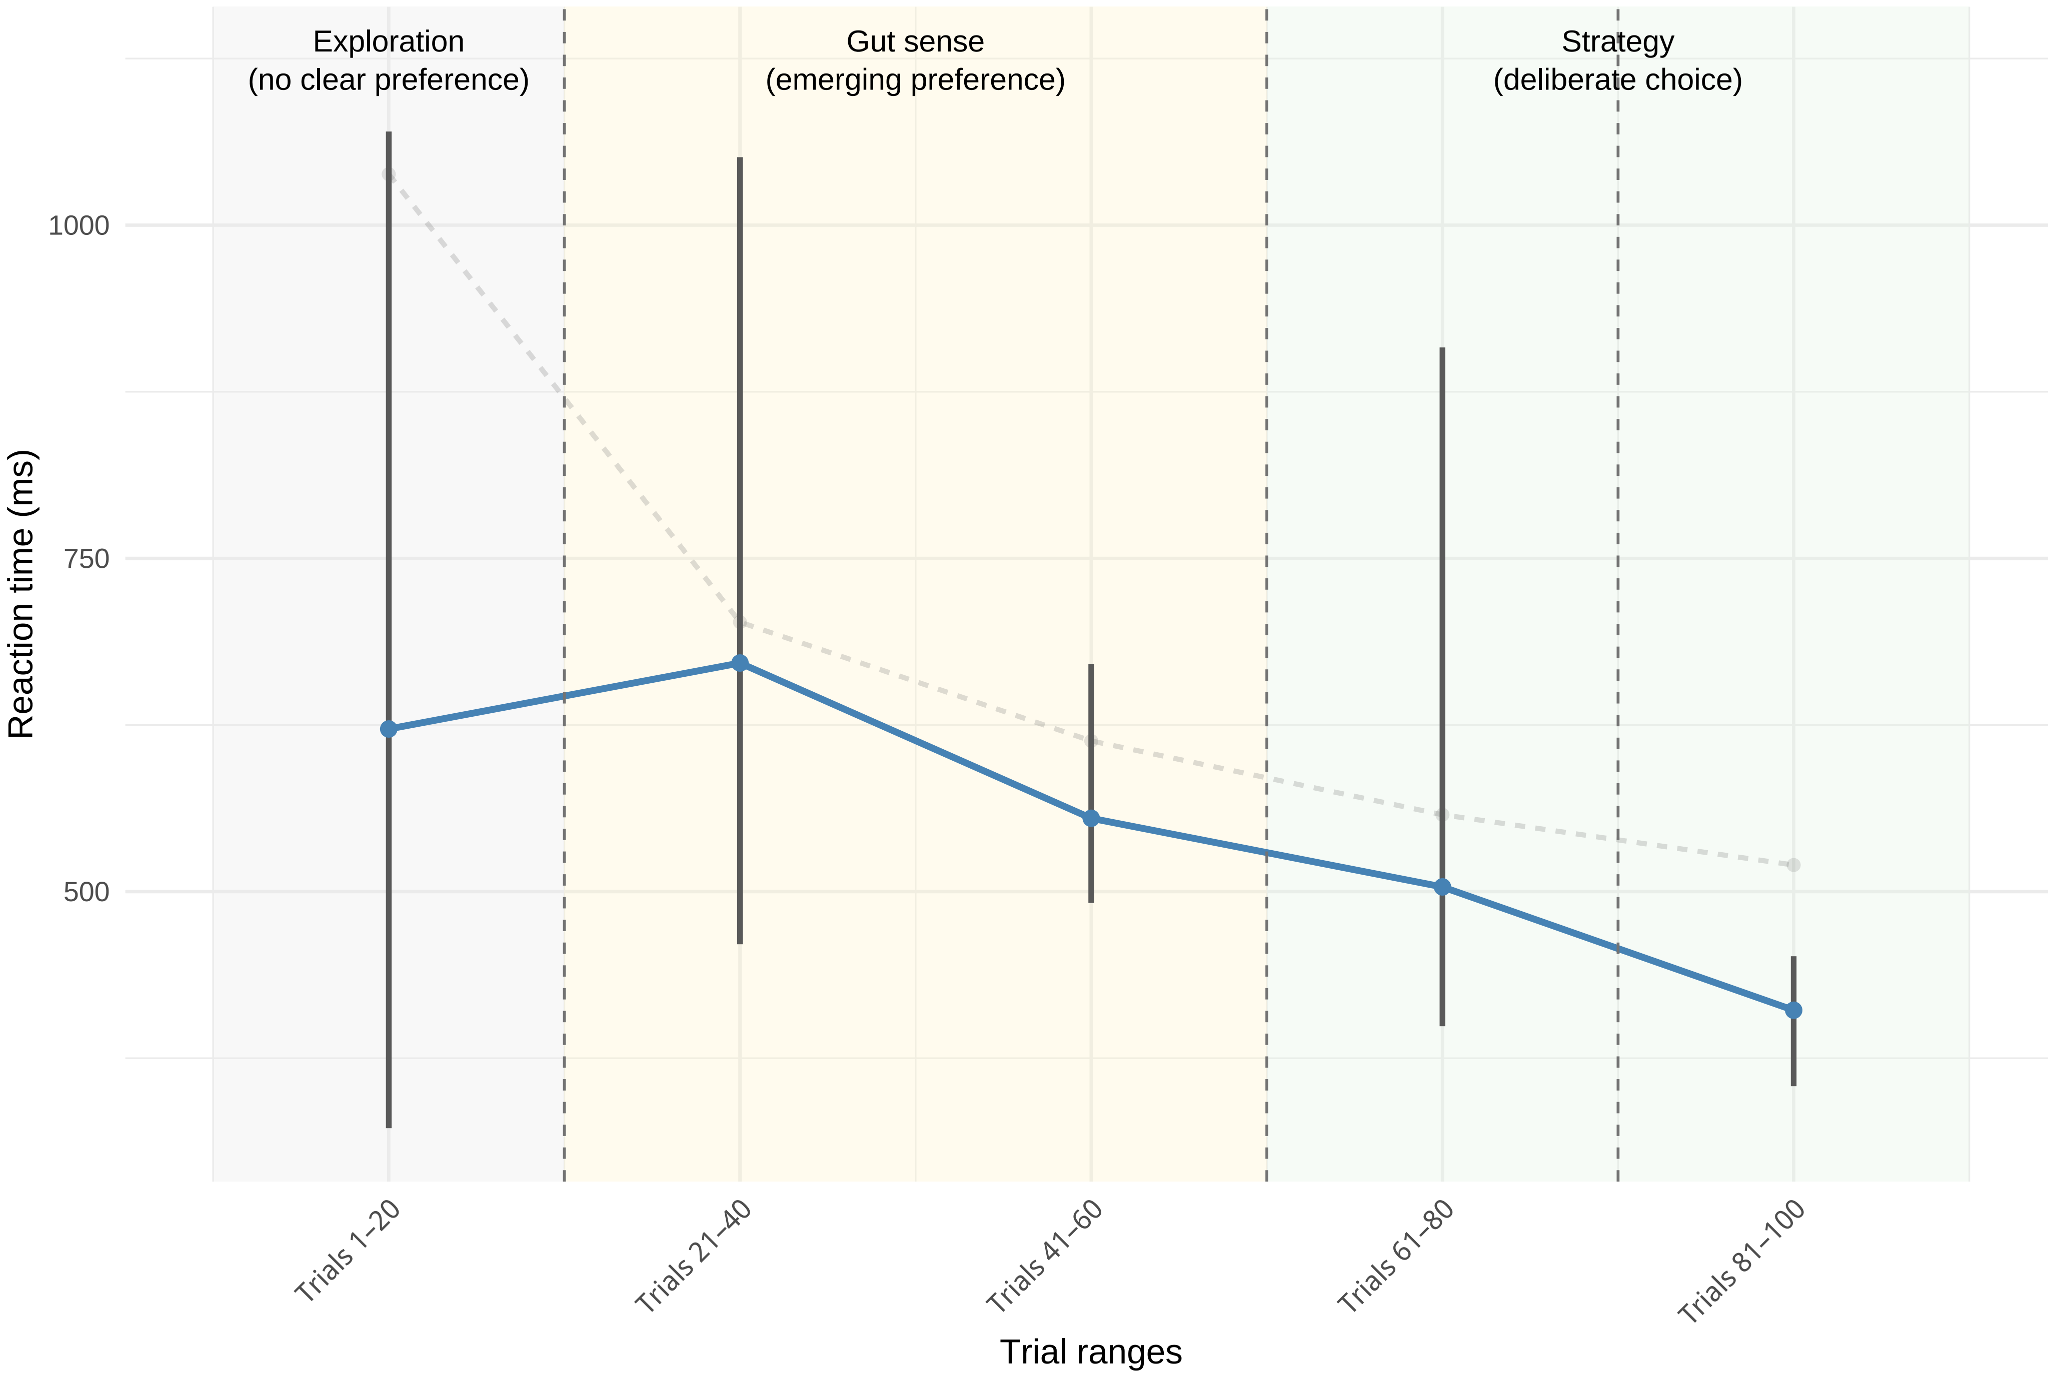

Figure 3 — Money earned (cumulative) (Subject 5)

Dashed red line = $0 (break-even). You started with a hypothetical $2000 loan; values above 0 mean you are in profit. Faint dashed grey = class average.
